PATHOLOGY REPORT

Clinical Information.	Soft tissue lesion located on the anterior maxillary labial gingiva in relation to the upper primary incisors.
Nature of specimen.	Incisional biopsy.

GROSS:

Soft tissue fragment measured 1.7x1.3x1 cm, totally embedded.

MICROSCOPIC:

Sections show intact surface stratified squamous epithelium. The underlying subepithelial connective tissue is expanded by an unencapsulated, highly cellular nodular proliferation. The lesion is predominantly characterized by numerous multinucleated, osteoclast-like giant cells evenly distributed within a richly vascularized stroma composed of plump, ovoid-to-spindle-shaped mononuclear cells. Abundant interstitial hemorrhage and extravasated red blood cells are dispersed throughout the background tissue. No cytological atypia or evidence of malignancy is identified.

DIAGNOSIS:

Upper anterior labial gum tissue, incisional biopsy:

- Giant cell epulis (Peripheral giant cell granuloma).
- Negative for malignancy.
