PATHOLOGY REPORT

Clinical Information.	Perineal fistula.
Nature of specimen.	Excision

GROSS:

Partially skin covered soft tissue fragment measured 2.7x0.3x0.8 cm.

PHOTOGRAPH

MICROSCOPIC:

Skin and underlying soft tissue containing a well-formed fistulous channel. The lining of the tract is dominantly composed of septic granulation tissue characterized by newly formed capillaries, stromal edema, and active fibroblastic proliferation. A dense inflammatory infiltrate is present, predominantly lymphoplasmacytic in composition, admixed with histiocytes and excess neutrophils. The surrounding tissue demonstrates variable degrees of fibrosis and reactive vascular changes. The adjacent squamous epithelium is partially denuded. No cytologic atypia, dysplasia, or invasive malignant process is identified in the examined sections.

DIAGNOSIS:

Perineal fistulous tract, excision

- Chronic active inflammation with granulation tissue and associated fibrosis (inflammatory fistula).
- Negative for malignancy
