PATHOLOGY REPORT

Clinical Information.	Debridement for a left-sided gluteal abscess and bed sore.
Nature of specimen.	Debridement

GROSS:

Soft tissue fragments collectively measured 3.5x2.8x1 cm, totally embedded.

MICROSCOPIC:

Fragments of markedly inflamed and necrotic fibrofatty tissue and skeletal muscle, showing marked infiltration by an acute and chronic inflammatory infiltrate, with prominent areas of abscess formation characterized by pools of viable and degenerated neutrophils admixed with fibrinopurulent debris. The surrounding stroma exhibits marked fat necrosis, organizing granulation tissue with prominent neovascularization, and reactive fibroblastic proliferation. Interspersed foci of hemorrhage and hemosiderin-laden macrophages are also present. No epithelial elements are identified. There is no evidence of atypia or malignancy.

DIAGNOSIS:

Debridement for a left-sided gluteal abscess and bed sore:

- Fibroadipose tissue and skeletal muscle with extensive necrosis, devitalization and abscess formation.
- Reactive granulation tissue with fat necrosis and fibrosis.
- Negative for malignancy.
