PATHOLOGY REPORT

|                       |                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clinical Information. | Follow-up upper GI endoscopy for a known history of reflux esophagitis with focal dysplasia was found to have an abnormal whitish mucosa in the lower esophagus that was biopsied to exclude dysplasia or malignancy, |
| Nature of specimen.   | Endoscopic biopsies.                                                                                                                                                                                                  |

GROSS:

Soft tissue fragments collectively measured 0.6 cm, totally embedded.

MICROSCOPIC:

Esophageal mucosal fragments showing hyperplastic stratified squamous epithelium with related mild chronic non specific inflammation. No evidence of dysplasia or malignancy in examined material.

DIAGNOSIS:

Esophagus, endoscopic biopsy :

- Hyperplastic squamous epithelium with chronic non-specific inflammation consistent with GERD.
- Negative for eosinophilic esophagitis.
- Negative for malignancy.
