PATHOLOGY REPORT

Clinical Information.	Pangastritis with two inflammatory antral polyps (biopsied), subepithelial bulge at the antral area.
Nature of specimen.	Endoscopic biopsy

GROSS:

Soft tissue fragments collectively measured 0.6 cm, totally embedded.

MICROSCOPIC:

Sections show gastric mucosa with polypoid foveolar hyperplasia, characterized by elongated, tortuous, and cystically dilated pits. The lamina propria is edematous and expanded by a mild chronic inflammatory infiltrate composed of lymphocytes and plasma cells, accompanied by mild glandular atrophy. There is mild active inflammation with scattered neutrophils infiltrating the foveolar and glandular epithelium. Examination of the luminal surface and mucus layers reveals curvilinear, rod-shaped bacterial organisms consistent with *Helicobacter pylori*. No evidence of atypia or malignancy.

DIAGNOSIS:

Stomach, endoscopic biopsy :

- Hyperplastic polyps.
- H. pylori associated mild atrophic gastritis with mild inflammatory activity .
- Negative for dysplasia or malignancy.
